Introduction

CBEP, like other National Estuary Programs will receive additional funding to support our programs via the "Bipartisan Infrastructure Law" signed into law last December.

EPA has recently released guidance for applying for those funds. A core component of the guidance is that overall, the NEP program should comply with the White House's "Justice 40" initiative, which requires that "at least 40% of the benefits and investments from BIL funding flow to disadvantaged communities."

EPA suggested that we use the National-scale EJSCREEN tools to help identify "disadvantaged communities" in our region. The EPA guidance goes on to suggest we focus on five demographic indicators:

- Percent low-income;
- Percent linguistically isolated;
- Percent less than high school education;
- Percent unemployed; and
- Low life expectancy.

This notebook builds on the work in "Calc_Indexes.pdf" to calculate data for the Casco Bay Watershed Census block groups, and calculates how Casco Bay Census block groups compare at National, Statewide, and Regional scales.

Load Libraries

Set Graphics Theme

This sets ggplot() graphics for no background, no grid lines, etc. in a clean graphic format.

```
theme_set(theme_classic())
```

Load Data

Folder References

I use folder references to allow limited indirection, thus making code from GitHub repositories more likely to run "out of the box".

```
data_folder <- "Original_Data"
#dir.create(file.path(getwd(), 'figures'), showWarnings = FALSE)</pre>
```

I use the "Original_Data" folder to retain data in the form originally downloaded. That minimizes the chances of inadvertently modifying the source data. All data was accessed via EJScreen. The 2021 EJSCREEN Data was accessed on July 26, 2022, at https://gaftp.epa.gov/EJSCREEN/2021/. I downloaded geodatabases, and open the geospatial data they contained in ArcGIS and exported the tabular attribute data to CSV files. That tabular CSV data is provided in the "Original Data" folder here.

Load Data

The Tabular data is quite extensive, which poses some data access challenges. The raw CSV file contains more than 200,000 records, and more than 100 columns. Most, but not all are numeric.

Save Data

```
write_csv(cb_data, "cb_block_groups_indexes.csv")
```

Calculate Thresholds

We have six different indexes, and we want threshold values for each at National, State, and Casco Bay Region levels. It's convenient to automate the calculations using a small function and the map() function.

Utility Function

This function calculates the 80th percentile (by default, anyway) of a named data column from a data frame. There is no error checking, so this is NOT appropriate for programming with out more work.

```
quantile_select_col <- function(.data, .col, .q = 0.8) {
   return(quantile(.data[,.col], .q, na.rm = TRUE))
}

the_data %>%
   quantile_select_col( "Index_Raw")

#> 80%
#> 31.15984
```

Calculations

I calculate a named vector of threshold values at National, State and Casco Bay Regional levels.

```
National <- map(nms, function(x) quantile_select_col(the_data, x))</pre>
National <- unlist(National) # Flatten List to numeric vector
names(National) <- nms</pre>
                              # Add Names
National
#>
           Index Raw
                         Index 5 Ptiles
                                            Index_4_Ptiles Index_best_Ptiles
#>
            31.15984
                               69.86830
                                                   71.20022
                                                                      71.34104
#>
                           PCA Index V2
        PCA Index V1
#>
            73.68687
                              154.05754
```

```
Maine <- map(nms,
             function(x) quantile_select_col(the_data[the_data$STATE_NAME == 'Maine',], x))
Maine <- unlist(Maine) # Flatten List to numeric vector</pre>
names(Maine) <- nms
                         # Add Names
Maine
#>
           Index Raw
                       Index 5 Ptiles
                                          Index_4_Ptiles Index_best_Ptiles
#>
           26.68095
                              59.35638
                                                59.25347
                                                            59.41836
#>
        PCA Index V1
                         PCA Index V2
                             131.38726
#>
            62.97380
Region <- map(nms, function(x) quantile_select_col(cb_data, x))</pre>
Region <- unlist(Region) # Flatten List to numeric vector
names(Region) <- nms
                          # Add Names
Region
#>
                       Index_5_Ptiles
                                          Index_4_Ptiles Index_best_Ptiles
           Index\_Raw
#>
                                                47.24771
            22.86673
                             47.00886
                                                          48.85200
#>
        PCA\_Index\_V1
                          PCA_Index_V2
#>
            52.69994
                             100.60834
thresholds <- bind rows(National, Maine, Region, .id = 'Scale') %>%
 mutate(Scale = c('National', 'Maine', 'Region'))
```

Calculate NUmber of Threshold Exceedences

I use a functional programming approach for calculating whether specific Casco Bay Census block groups exceed each threshold. Here I pass both a dataframe and a names list or vector containing the thresholds.

Utility Function

```
threshold_compare <- function(.data, .thresholds, .col) {</pre>
  return(.data[.col] > .thresholds[.col])
National_Exceeds <- map(as.list(nms),</pre>
                        function(x) threshold_compare(cb_data, National, x))
National_Exceeds <- as.data.frame(National_Exceeds)</pre>
names(National_Exceeds) <- nms</pre>
unlist(map(National_Exceeds, sum, na.rm = TRUE))
           Index Raw Index 5 Ptiles
                                           Index_4_Ptiles Index_best_Ptiles
#>
               2
                           0
                                                        5
#>
        PCA\_Index\_V1
                          PCA_Index_V2
#>
Maine_Exceeds <- map(as.list(nms),</pre>
                     function(x) threshold_compare(cb_data, Maine, x))
Maine_Exceeds <- as.data.frame(Maine_Exceeds)</pre>
names(Maine Exceeds) <- nms</pre>
unlist(map(Maine_Exceeds, sum, na.rm = TRUE))
           Index_Raw Index_5_Ptiles Index_4_Ptiles Index_best_Ptiles
#>
#>
                             10
                                                       15
```
